Evaluation of Structural Matrices

Choice of Property Formulation

Today we will study the properties of structural matrices, that is the operators that relate the vector of system coordinates x and its time derivatives \dot{x} and \ddot{x} to the forces acting on the system nodes, $f_{\rm S}$, $f_{\rm D}$ and $f_{\rm I}$, respectively.

In the end, we will see again the solution of a *MDOF* problem by superposition, and in general today we will revisit many of the subjects of our previous class, but you know that a bit of reiteration is really good for developing minds.

Today we will study the properties of structural matrices, that is the operators that relate the vector of system coordinates x and its time derivatives \dot{x} and \ddot{x} to the forces acting on the system nodes, f_S , f_D and f_I , respectively.

In the end, we will see again the solution of a *MDOF* problem by superposition, and in general today we will revisit many of the subjects of our previous class, but you know that a bit of reiteration is really good for developing minds.

Orthogonality Relationships Additional Orthogonality Relationships

Evaluation of Structural Matrices

Choice of Property Formulation

We already met the mass and the stiffness matrix, M and K, and tangentially we introduced also the dampig matrix C. We have seen that these matrices express the linear relation that holds between the vector of system coordinates x and its time derivatives \dot{x} and \ddot{x} to the forces acting on the system nodes, f_S , f_D and f_I , elastic, damping and inertial force vectors.

$$M\ddot{x} + C\dot{x} + Kx = p(t)$$

 $f_1 + f_D + f_S = p(t)$

Also, we know that M and K are symmetric and definite positive, and that it is possible to uncouple the equation of motion expressing the system coordinates in terms of the eigenvectors, $\mathbf{x}(t) = \sum q_i \psi_i$, where the q_i are the modal coordinates and the eigenvectors ψ_i are the non-trivial solutions to the characteristic equation,

$$\left(\textbf{\textit{K}}-\omega^{2}\textbf{\textit{M}}\right)\psi=\textbf{0}$$

Free Vibrations

Structural Matrices

From the homogeneous, undamped problem

$$M\ddot{x} + Kx = 0$$

introducing separation of variables

$$\mathbf{x}(t) = \mathbf{\psi} \left(A \sin \omega t + B \cos \omega t \right)$$

we wrote the homogeneous linear system

$$(K - \omega^2 M) \psi = 0$$

whose non-trivial solutions ψ_i for ω_i^2 such that $\left\| \mathbf{K} - \omega_i^2 \mathbf{M} \right\| = 0$ are the eigenvectors. It was demonstrated that, for each pair of distint *eigenvalues* ω_r^2 and ω_s^2 , the corresponding eigenvectors obey the ortogonality condition,

$$\psi_s^{\mathcal{T}} \boldsymbol{M} \psi_r = \delta_{\textit{rs}} M_r, \quad \psi_s^{\mathcal{T}} \boldsymbol{K} \psi_r = \delta_{\textit{rs}} \omega_r^2 M_r.$$

Evaluation of Structural Matrices

Choice of Property Formulation

From

$$M \psi_s = \omega_s^{-2} K \psi_s$$

premultiplying by $\psi_r^T M K^{-1}$ we have

$$\boldsymbol{\psi}_{r}^{T}\boldsymbol{M}\boldsymbol{K}^{-1}\boldsymbol{M}\,\boldsymbol{\psi}_{s}=\boldsymbol{\omega}_{s}^{-2}\boldsymbol{\psi}_{r}^{T}\boldsymbol{M}\,\boldsymbol{\psi}_{s}=\delta_{rs}\frac{M_{s}}{\omega_{s}^{2}}$$

premultiplying the first eq. by $\psi_r^T \left(M K^{-1} \right)^2$ we have

$$\psi_{\textit{r}}^{\textit{T}} \left(\textit{M}\textit{K}^{-1}\right)^{2} \textit{M} \psi_{\textit{s}} = \omega_{\textit{s}}^{-2} \psi_{\textit{r}}^{\textit{T}} \textit{M} \textit{K}^{-1} \textit{M} \psi_{\textit{s}} = \delta_{\textit{rs}} \frac{\textit{M}_{\textit{s}}}{\omega_{\textit{s}}^{4}}$$

and, generalizing,

$$\psi_{\textit{r}}^{\textit{T}} \left(\textit{M}\textit{K}^{-1}\right)^{\textit{b}} \textit{M} \, \psi_{\textit{s}} = \delta_{\textit{rs}} \frac{\textit{M}_{\textit{s}}}{\omega_{\textit{s}}^{2\textit{b}}}$$

Defining
$$X_{rs}(k) = \psi_r^T M (M^{-1}K)^k \psi_s$$
 we have

$$\begin{cases} X_{rs}(0) = \psi_r^T M \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^0 M_s \\ X_{rs}(1) = \psi_r^T K \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^1 M_s \\ X_{rs}(2) = \psi_r^T \left(K M^{-1} \right)^1 K \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^2 M_s \\ \dots \\ X_{rs}(n) = \psi_r^T \left(K M^{-1} \right)^{n-1} K \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^n M_s \end{cases}$$

Observing that
$$(\mathbf{M}^{-1}\mathbf{K})^{-1} = (\mathbf{K}^{-1}\mathbf{M})^{1}$$

$$\begin{cases} X_{rs}(-1) = \psi_r^T \left(\mathbf{M} \mathbf{K}^{-1} \right)^1 \mathbf{M} \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^{-1} M_s \\ \dots \\ X_{rs}(-n) = \psi_r^T \left(\mathbf{M} \mathbf{K}^{-1} \right)^n \mathbf{M} \psi_s &= \delta_{rs} \left(\omega_s^2 \right)^{-n} M_s \end{cases}$$

finally

$$X_{rs}(k) = \delta_{rs} \omega_s^{2k} M_s$$
 for $k = -\infty, ..., \infty$.

Choice of

Property Formulation

Momentarily disregarding inertial effects, each node shall be in equilibrium under the action of the external forces and the elastic forces, hence taking into accounts all the nodes, all the external forces and all the elastic forces it is possible to write the vector equation of equilibrium

$$p = f_{S}$$

and, substituting in the previos vector expression of the displacements

$$x = F f_S$$

Example
Geometric
Stiffness
External Loading

Choice of Property

The *stiffness matrix* K can be simply defined as the inverse of the flexibility matrix F,

$$K = F^{-1}$$
.

Alternatively the single coefficient k_{ij} can be defined as the external force (equal and opposite to the corresponding elastic force) applied to the *DOF* number i that gives place to a displacement vector $\mathbf{x}^{(j)} = \left\{x_n\right\} = \left\{\delta_{nj}\right\}$, where all the components are equal to zero, except for $\mathbf{x}^{(j)}_j = 1$. Collecting all the $\mathbf{x}^{(j)}$ in a matrix \mathbf{X} , it is $\mathbf{X} = \mathbf{I}$ and we have, writing all the equations at once,

$$X = I = F[k_{ij}], \Rightarrow [k_{ij}] = K = F^{-1}.$$

Finally,

$$p = f_S = K x$$
.

Structural Matrices Flexibility Matrix Example

Evaluation of

Stiffness Matrix Strain Energy

Symmetry Direct

Assemblage Example Mass Matrix Consistent Mass

Matrix
Discussion
Damping Matrix
Example
Geometric

Stiffness External Loading

Choice of Property Formulation

The elastic strain energy V can be written in terms of displacements and external forces,

$$V = \frac{1}{2} \boldsymbol{p}^T \boldsymbol{x} = \frac{1}{2} \begin{cases} \boldsymbol{p}^T \underbrace{\boldsymbol{F} \, \boldsymbol{p}}_{\boldsymbol{x}}, \\ \underbrace{\boldsymbol{x}^T \boldsymbol{K}}_{\boldsymbol{p}^T} \boldsymbol{x}. \end{cases}$$

Because the elastic strain energy of a stable system is always greater than zero, \boldsymbol{K} is a positive definite matrix. On the other hand, for an unstable system, think of a compressed beam, there are displacement patterns that are associated to zero strain energy.

Discussion Damping Matrix

Example Geometric Stiffness

External Loading Choice of

Property Formulation

Two sets of loads p^A and p^B are applied, one after the other, to an elastic system; the work done is

$$V_{AB} = rac{1}{2} {oldsymbol{
ho}^A}^T {oldsymbol{x}^A} + {oldsymbol{
ho}^A}^T {oldsymbol{x}^B} + rac{1}{2} {oldsymbol{
ho}^B}^T {oldsymbol{x}^B}.$$

If we revert the order of application the work is

$$V_{BA} = \frac{1}{2} \boldsymbol{p}^{BT} \boldsymbol{x}^{B} + \boldsymbol{p}^{BT} \boldsymbol{x}^{A} + \frac{1}{2} \boldsymbol{p}^{AT} \boldsymbol{x}^{A}.$$

The total work being independent of the order of loading,

$$p^{AT}x^B = p^{BT}x^A$$
.

Expressing the displacements in terms of F,

$$p^{AT}Fp^{B}=p^{BT}Fp^{A},$$

both terms are scalars so we can write

$$p^{A^T} F p^B = (p^{B^T} F p^A)^T = p^{A^T} F^T p^B.$$

Because this equation holds for every p, we conclude that

$$\mathbf{F} = \mathbf{F}^T$$
.

The inverse of a symmetric matrix is symmetric, hence

$$K = K^T$$
.

Choice of Property Formulation

For the kind of *structures* we mostly deal with in our examples, problems, exercises and assignments, that is *simple structures*, it is usually convenient to compute the flexibility matrix applying the Principle of Virtual Displacements (we have seen an example last week) and inverting the flexibility to obtain the stiffness matrix. $K = F^{-1}$.

For general structures, large and/or complex, the PVD approach cannot work in practice, as the number of degrees of freedom necessary to model the structural behaviour exceed our ability to do pencil and paper computations... Different methods are required to construct the stiffness matrix for such large, complex structures. Enters the Finite Element Method.

Choice of Property Formulation

The most common procedure to construct the matrices that describe the behaviour of a complex system is the *Finite Element Method*, or *FEM*. The procedure can be sketched in the following terms:

- ▶ the structure is subdivided in non-overlapping portions, the *finite elements*, bounded by *nodes*, connected by the same nodes,
- ▶ the state of the structure can be described in terms of a vector *x* of generalized *nodal displacements*,
- ▶ there is a mapping between element and structure DOF's, $i_{el} \mapsto r$,
- between an element nodal displacements and forces,
- ▶ for each FE, all local k_{ij} 's are contributed to the global stiffness k_{rs} 's, with $i \mapsto r$ and $j \mapsto s$, taking in due consideration differences between local and global systems of reference.

Note that in the r-th global equation of equilibrium we have internal forces caused by the nodal displacements of the FE that have nodes $i_{\rm el}$ such that $i_{\rm el}\mapsto r$, thus implying that global K is a banded matrix.

Note that in the r-th global equation of equilibrium we have internal forces caused by the nodal displacements of the FE that have nodes $i_{\rm el}$ such that $i_{\rm el} \mapsto r$, thus implying that global K is a banded matrix.

Consider a 2-D inextensible beam element, that has 4 *DOF*, namely two transverse end displacements x_1 , x_2 and two end rotations, x_3 , x_4 . The element stiffness is computed using 4 shape functions ϕ_i , the transverse displacement being $v(s) = \sum_i \phi_i(s) x_i$, the different ϕ_i are such all end displacements or rotation are zero, except the one corresponding to index i.

The shape functions for a beam are

$$\begin{aligned} & \phi_1(s) = 1 - 3\left(\frac{s}{L}\right)^2 + 2\left(\frac{s}{L}\right)^3, & \phi_2(s) = 3\left(\frac{s}{L}\right)^2 - 2\left(\frac{s}{L}\right)^3, \\ & \phi_3(s) = s\left(1 - \left(\frac{s}{L}\right)^2\right), & \phi_4(s) = s\left(\left(\frac{s}{L}\right)^2 - \left(\frac{s}{L}\right)\right). \end{aligned}$$

Stiffness External Loading

The element stiffness coefficients can be computed using, what else, the PVD: we compute the external virtual work done by a variation δx_i by the force due to a unit displacement x_i , that is k_{ii} ,

$$\delta W_{\rm ext} = \delta x_i k_{ij}$$
,

the virtual internal work is the work done by the variation of the curvature, $\delta x_i \phi_i''(s)$ by the bending moment associated with a unit x_j , $\phi_j''(s) EJ(s)$,

$$\delta W_{\rm int} = \int_0^L \delta x_i \varphi_i''(s) \varphi_j''(s) EJ(s) \, \mathrm{d} s.$$

Choice of Property Formulation

The mass matrix maps the nodal accelerations to nodal inertial forces, and the most common assumption is to concentrate all masses in nodal point masses, without rotational inertia, computed *lumping* a fraction of each element mass (or a fraction of the supported mass) on all its bounding nodes.

This procedure leads to a so called *lumped* mass matrix, a diagonal matrix with diagonal elements greater than zero for all the translational degrees of freedom, and diagonal elements equal to zero for angular degrees of freedom. The mass matrix is definite positive *only* if all the structure *DOF*'s are translational degrees of freedom, otherwise *M* is semi-definite positive and the eigenvalue procedure is not directly applicable. This problem can be overcome either by using a *consistent* mass matrix or using the *static* condensation procedure.

Example

External Loading

A consistent mass matrix is built using the rigorous *FEM* procedure, computing the nodal reactions that equilibrate the distributed inertial forces that develop in the element due to a linear combination of inertial forces.

Using our beam example as a reference, consider the inertial forces associated with a single nodal acceleration \ddot{x}_j , $f_{i,j}(s) = m(s) \varphi_j(s) \ddot{x}_j$ and denote with $m_{ij} \ddot{x}_j$ the reaction associated with the *i*-nth degree of freedom of the element, by the PVD

$$\delta x_i m_{ij} \ddot{x}_j = \int \delta x_i \varphi_i(s) m(s) \varphi_j(s) ds \ddot{x}_j$$

simplifying

$$m_{ij} = \int m(s) \phi_i(s) \phi_j(s) ds.$$

For $m(s) = \overline{m} = \text{const.}$

$$\mathbf{f_I} = \frac{\overline{m}L}{420} \begin{bmatrix} 156 & 54 & 22L & -13L \\ 54 & 156 & 13L & -22L \\ 22L & 13L & 4L^2 & -3L^2 \\ -13L & -22L & -3L^2 & 4L^2 \end{bmatrix} \ddot{\mathbf{x}}$$

Pro

- some convergence theorem of FEM theory holds only if the mass matrix is consistent,
- sligtly more accurate results,
- no need for static condensation.

Contra

- M is no more diagonal, heavy computational aggravation,
- static condensation is computationally beneficial, inasmuch it reduces the global number of degrees of freedom.

For each element $c_{ij} = \int c(s)\phi_i(s)\phi_j(s) ds$ and the damping matrix C can be assembled from element contributions.

However, using the FEM $C^* = \Psi^T C \Psi$ is not diagonal and the modal equations are uncoupled!

The alternative is to write directly the global damping matrix, in terms of the underdetermined coefficients c_b ,

$$C = \sum_{b} c_{b} M \left(M^{-1} K \right)^{b}.$$

Choice of Property Formulation

With our definition of *C*.

$$oldsymbol{C} = \sum_b \mathfrak{c}_b oldsymbol{M} \left(oldsymbol{M}^{-1} oldsymbol{K}
ight)^b$$
 ,

assuming normalized eigenvectors, we can write the individual component of $\mathbf{C}^* = \mathbf{\Psi}^T \mathbf{C} \mathbf{\Psi}$

$$c_{ij}^{\star} = \mathbf{\psi}_{i}^{\mathsf{T}} \mathbf{C} \, \mathbf{\psi}_{j} = \delta_{ij} \sum_{b} \mathfrak{c}_{b} \omega_{j}^{2b}$$

due to the additional orthogonality relations, we recognize that now C^* is a diagonal matrix.

$$C_j = \psi_j^T \mathbf{C} \psi_j = \sum_b \mathfrak{c}_b \omega_j^{2b} = 2\zeta_j \omega_j$$

$$\mathbf{C} = \sum_{b} \mathfrak{c}_{b} \mathbf{M} \left(\mathbf{M}^{-1} \mathbf{K} \right)^{b}$$
 ,

assuming normalized eigenvectors, we can write the individual component of $\mathbf{C}^{\star} = \mathbf{\Psi}^{T} \mathbf{C} \mathbf{\Psi}$

$$c_{ij}^{\star} = \psi_i^T C \psi_j = \delta_{ij} \sum_b \mathfrak{c}_b \omega_j^{2b}$$

due to the additional orthogonality relations, we recognize that now C^* is a diagonal matrix.

Introducing the modal damping C_j we have

$$C_j = \boldsymbol{\psi}_j^T \boldsymbol{C} \, \boldsymbol{\psi}_j = \sum_b \mathfrak{c}_b \omega_j^{2b} = 2\zeta_j \omega_j$$

and we can write a system of linear equations in the c_h .

Choice of

Choice of Property Formulation

Direct

We want a fixed, 5% damping ratio for the first three modes, taking note that the modal equation of motion is

$$\ddot{q}_i + 2\zeta_i \omega_i \dot{q}_i + \omega_i^2 q_i = p_i^*$$

Using

$$C = \mathfrak{c}_0 M + \mathfrak{c}_1 K + \mathfrak{c}_2 K M^{-1} K$$

we have

$$2\times0.05 \left\{\begin{matrix} \omega_1\\ \omega_2\\ \omega_3 \end{matrix}\right\} = \begin{bmatrix} 1 & \omega_1^2 & \omega_1^4\\ 1 & \omega_2^2 & \omega_2^4\\ 1 & \omega_3^2 & \omega_3^4 \end{bmatrix} \left\{\begin{matrix} \mathfrak{c}_0\\ \mathfrak{c}_1\\ \mathfrak{c}_2 \end{matrix}\right\}$$

Solving for the \mathfrak{c} 's and substituting above, the resulting damping matrix is orthogonal to every eigenvector of the system, for the first three modes, leads to a modal damping ratio that is equal to 5%.

Negative damping? No, thank you: use only an even number of terms.

Direct

Property Formulation

A common assumption is based on a linear approximation, for a beam element

It is possible to compute the geometrical stiffness matrix using *FEM*, shape functions and PVD,

$$k_{\mathsf{G},ij} = \int N(s) \phi_i'(s) \phi_j'(s) \,\mathrm{d}s,$$

for constant N

$$K_{G} = \frac{N}{30L} \begin{bmatrix} 36 & -36 & 3L & 3L \\ -36 & 36 & -3L & -3L \\ 3L & -3L & 4L^{2} & -L^{2} \\ 3L & -3L & -L^{2} & 4L^{2} \end{bmatrix}$$

Choice of Property Formulation

Following the same line of reasoning that we applied to find nodal inertial forces, by the PVD and the use of shape functions we have

$$p_i(t) = \int p(s,t) \varphi_i(s) \, \mathrm{d} s.$$

For a constant, uniform load $p(s,t)=\overline{p}={\rm const.}$ applied on a beam element,

$$\boldsymbol{p} = \overline{p}L \left\{ \frac{1}{2} \quad \frac{1}{2} \quad \frac{L}{12} \quad -\frac{L}{12} \right\}^T$$

Matrices

Going back to the homogeneous problem, with obvious positions we can write

$$\left(\overline{\textbf{\textit{K}}}-\omega^2\overline{\textbf{\textit{M}}}\right)\psi_{\textit{A}}=\textbf{0}$$

but the ψ_A are only part of the structural eigenvectors, because in essentially every application we must consider also the other DOF's, so we write

$$\psi_i = egin{cases} \psi_{A,i} \ \psi_{B,i} \end{cases}$$
 , with $\psi_{B,i} = \mathcal{K}_{BB}^{-1} \mathcal{K}_{BA} \psi_{A,i}$

Evaluation of Structural Matrices

Condensation Example

Giacomo Boffi

Choice of Property Formulation Static

$$\mathbf{K} = \frac{2EJ}{L^3} \begin{bmatrix} 12 & 3L & 3L \\ 3L & 6L^2 & 2L^2 \\ 3L & 2L^2 & 6L^2 \end{bmatrix}$$

Disregarding the factor $2EJ/L^3$,

$$K_{BB} = L^2 \begin{bmatrix} 6 & 2 \\ 2 & 6 \end{bmatrix}$$
, $K_{BB}^{-1} = \frac{1}{32L^2} \begin{bmatrix} 6 & -2 \\ -2 & 6 \end{bmatrix}$, $K_{AB} = \begin{bmatrix} 3L & 3L \end{bmatrix}$

The matrix \overline{K} is

$$\overline{K} = \frac{2EJ}{L^3} \left(12 - K_{AB} K_{BB}^{-1} K_{AB}^{\mathsf{T}} \right) = \frac{39EJ}{2L^3}$$
