How many eigenvectors?

To understand how many eigenvectors we have to use in a modal analysis, we must consider two factors, the loading shape and the excitation frequency.

In the following, we'll consider *only* external loadings whose dependance on time and space can be separated, as in

$$\mathbf{p}(\mathbf{x}, t) = \mathbf{r} f(t),$$

so that we can regard separately the two aspects of the problem.

It is worth noting that earthquake loadings are precisely of this type:

$$\vec{p}(\vec{x}, t) = \mathbf{M}\tilde{\vec{r}}\ddot{u}_g$$

where the vector $\tilde{\vec{r}}$ is used to choose the structural dof's that are *excited* by the ground motion component under consideration.

$\tilde{\vec{r}}$ is an incidence vector, often simply a vector of ones and zeroes where the ones stay for the inertial forces that are excited by a specific component of the earthquake ground acceleration.

Introduction

It is worth noting that earthquake loadings are precisely of this type:

$$\vec{p}(\vec{x}, t) = \mathbf{M}\vec{r}\ddot{u}_g$$

where the vector \vec{r} is used to choose the structural dof's that are *excited* by the ground motion component under consideration.

\vec{r} is an incidence vector, often simply a vector of ones and zeroes where the ones stay for the inertial forces that are excited by a specific component of the earthquake ground acceleration.

Multiplication of \mathbf{M} and division of \ddot{u}_g by g , acceleration of gravity, serves to show a dimensional load vector multiplied by an adimensional function.

$$\begin{aligned}\vec{p}(\vec{x}, t) &= g \mathbf{M}\vec{r} \frac{\ddot{u}_g(t)}{g} \\ &= \mathbf{r}^g f_g(t)\end{aligned}$$

For a given loading \mathbf{r} the modal participation factor Γ_i is proportional to the work done by the modal displacement $q_i \boldsymbol{\psi}_i^T$ for the given loading \mathbf{r} :

- if the mode shape and the loading shape are approximately equal (equal signs, component by component), the work (dot product) is maximized,
- if the mode shape is significantly different from the loading (different signs), there is some amount of cancellation and the value of the Γ 's will be reduced.

Modal Loads Expansion

- 1 A modal load component works *only* for the displacements associated with the corresponding eigenvector,

$$\boldsymbol{\psi}_j^T \mathbf{r}_i = a_i \boldsymbol{\psi}_j^T \mathbf{M} \boldsymbol{\psi}_i = \delta_{ij} a_i M_i.$$

- 2 Comparing $\boldsymbol{\psi}_j^T \mathbf{r} = \boldsymbol{\psi}_j^T \sum_i \mathbf{M} \boldsymbol{\psi}_i a_i = \delta_{ij} M_i a_i$ with the definition of $\Gamma_i = \boldsymbol{\psi}_i^T \mathbf{r} / M_i$, we conclude that $a_i \equiv \Gamma_i$ and finally write

$$\mathbf{r}_i = \Gamma_i \mathbf{M} \boldsymbol{\psi}_i.$$

- 3 The modal load contributions can be collected in a matrix: with $\boldsymbol{\Gamma} = \text{diag } \Gamma_i$ we have

$$\mathbf{R} = \mathbf{M} \boldsymbol{\Psi} \boldsymbol{\Gamma}.$$

Equivalent Static Forces

For mode i , the equation of motion is

$$\ddot{q}_i + 2\zeta_i\omega_i\dot{q}_i + \omega_i^2q_i = \Gamma_i f(t)$$

with $q_i = \Gamma_i D_i$, we can write, to single out the dependency on the modulating function,

$$\ddot{D}_i + 2\zeta_i\omega_i\dot{D}_i + \omega_i^2D_i = f(t)$$

The modal contribution to displacement is

$$\mathbf{x}_i = \Gamma_i \boldsymbol{\psi}_i D_i(t)$$

and the modal contribution to elastic forces $\mathbf{f}_i = \mathbf{K} \mathbf{x}_i$ can be written (being $\mathbf{K} \boldsymbol{\psi}_i = \omega_i^2 \mathbf{M} \boldsymbol{\psi}_i$) as

$$\mathbf{f}_i = \mathbf{K} \mathbf{x}_i = \Gamma_i \mathbf{K} \boldsymbol{\psi}_i D_i = \omega_i^2 (\Gamma_i \mathbf{M} \boldsymbol{\psi}_i) D_i = \mathbf{r}_i \omega_i^2 D_i$$

Equivalent Static Response

The response can be determined by superposition of the effects of these pseudo-static forces $\mathbf{f}_i = \mathbf{r}_i \omega_i^2 D_i(t)$.

If a required response quantity (be it a nodal displacement, a bending moment in a beam, the total shear force in a building storey, etc etc) is indicated by $s(t)$, we can compute with a *static calculation* (usually using the *FEM* model underlying the dynamic analysis) the modal static contribution s_i^{st} and write

$$s(t) = \sum s_i^{\text{st}}(\omega_i^2 D_i(t)) = \sum s_i(t),$$

where the modal contribution to response $s_i(t)$ is given by

- 1** static analysis using \mathbf{r}_i as the static load vector,
- 2** dynamic amplification using the factor $\omega_i^2 D_i(t)$.

Giacomo Boffi

Say that the static response due to \mathbf{r} is denoted by s^{st} , then $s_i(t)$, the modal contribution to response $s(t)$, can be written

$$s_i(t) = s_i^{\text{st}} \omega_i^2 D_i(t) = s^{\text{st}} \frac{s_i^{\text{st}}}{s^{\text{st}}} \omega_i^2 D_i(t) = \bar{s}_i s^{\text{st}} \omega_i^2 D_i(t).$$

We have introduced $\bar{s}_i = \frac{s_i^{\text{st}}}{s^{\text{st}}}$, the *modal contribution factor*, the ratio of the modal static contribution to the total static response.

The \bar{s}_i are dimensionless, are independent from the eigenvector scaling procedure and their sum is unity, $\sum \bar{s}_i = 1$.

Introduction

Modal
participation
factor

Dynamic
magnification
factor

Static
Correction

Maximum Response

Denote by D_{i0} the maximum absolute value (or *peak*) of the pseudo displacement time history,

$$D_{i0} = \max_t \{|D_i(t)|\}.$$

It will be

$$s_{i0} = \bar{s}_i s^{\text{st}} \omega_i^2 D_{i0}.$$

The dynamic response factor for mode i , \mathfrak{R}_{di} is defined by

$$\mathfrak{R}_{di} = \frac{D_{i0}}{D_{i0}^{\text{st}}}$$

where D_{i0}^{st} is the peak value of the static pseudo displacement

$$D_i^{\text{st}} = \frac{f(t)}{\omega_i^2}, \quad \rightarrow \quad D_{i0}^{\text{st}} = \frac{f_0}{\omega_i^2}.$$

Maximum Response

With $f_0 = \max\{|f(t)|\}$ the peak pseudo displacement is

$$D_{i0} = \mathfrak{R}_{di} f_0 / \omega_i^2$$

and the peak of the modal contribution is

$$s_{i0}(t) = \bar{s}_i s^{\text{st}} \omega_i^2 D_{i0}(t) = f_0 s^{\text{st}} \bar{s}_i \mathfrak{R}_{di}$$

Truncation

tion
Support Exc.

Giacomo Boffi

Introduction

Modal
participation
factor

Dynamic
magnification
factor

Static
Correction

Maximum Response

With $f_0 = \max\{|f(t)|\}$ the peak pseudo displacement is

$$D_{i0} = \Re_{di} f_0 / \omega_i^2$$

and the peak of the modal contribution is

$$s_{i0}(t) = \bar{s}_i s^{\text{st}} \omega_i^2 D_{i0}(t) = f_0 s^{\text{st}} \bar{s}_i \Re_{di}$$

The first two terms are independent of the mode, the last are independent from each other and their product is the factor that influences the modal contributions.

Note that this product has the sign of \bar{s}_i , as the dynamic response factor is always positive.

MCF's example

The following table (from Chopra, 2nd ed.) displays the \bar{s}_i and their partial sums for a shear-type, 5 floors building where all the storey masses are equal and all the storey stiffnesses are equal too. The response quantities chosen are \bar{x}_{5n} , the MCF's to the top displacement and \bar{V}_n , the MCF's to the base shear, for two different load shapes.

Static Modal Components

The static modal displacement component $\mathbf{x}_j, j > n_{dy}$ can be written

$$x_j(t) = \boldsymbol{\psi}_j q_j(t) \approx \frac{\boldsymbol{\psi}_j \boldsymbol{\psi}_j^T}{K_j} \mathbf{p}(t) = \mathbf{F}_j \mathbf{p}(t)$$

The *modal flexibility matrix* is defined by

$$\mathbf{F}_j = \frac{\boldsymbol{\psi}_j \boldsymbol{\psi}_j^T}{K_j}$$

and is used to compute the j -th mode static deflections due to the applied load vector.

The total displacements, the dynamic contributions and the static correction, for $\mathbf{p}(t) = \mathbf{r} f(t)$, are then

$$\mathbf{x} \approx \sum_1^{n_{dy}} \boldsymbol{\psi}_j q_j(t) + f(t) \sum_{n_{dy}+1}^N \mathbf{F}_j \mathbf{r}.$$

Correction

Alternative Formulation

This problem can be obviated computing the total static displacements, $\mathbf{x}_{st}^{total} = \mathbf{K}^{-1}\mathbf{p}(t)$, and subtracting the static displacements due to the first n_{dy} modes...

$$\sum_{n_{dy}}^N \mathbf{F}_j \mathbf{r} f(t) = \mathbf{K}^{-1} \mathbf{r} f(t) - \sum_1^{n_{dy}} \mathbf{F}_j \mathbf{r} f(t) = f(t) \left(\mathbf{K}^{-1} - \sum_1^{n_{dy}} \mathbf{F}_j \right) \mathbf{r},$$

so that the corrected total displacements have the expression

$$\mathbf{x} \approx \sum_1^{n_{dy}} \boldsymbol{\psi}_i q_i(t) + f(t) \left(\mathbf{K}^{-1} - \sum_1^{n_{dy}} \mathbf{F}_i \right) \mathbf{r},$$

The constant term (a generalized displacement vector) following $f(t)$ can be computed with the information in our posses at the moment we begin the integration of the modal equations of motion.

Introduction to Numerical Integration

When we reviewed the numerical integration methods, we said that some methods are unconditionally stable and others are conditionally stable, that is the response *blows-out* if the time step h is great with respect to the natural period of vibration, $h > \frac{T_n}{a}$, where a is a constant that depends on the numerical algorithm.

For *MDOF* systems, the relevant T is the one associated with the highest mode present in the structural model, so for moderately complex structures it becomes impossibile to use a conditionally stable algorithm. In the following, two unconditionally stable algorithms will be analysed, i.e., the constant acceleration method, that we already know, and the new Wilson's θ method.

Introduction

**Constant
Acceleration**

Wilson's Theta
Method

Constant Acceleration, preliminaries

- The initial conditions are known:

$$\mathbf{x}_0, \quad \dot{\mathbf{x}}_0, \quad \mathbf{p}_0, \quad \rightarrow \quad \ddot{\mathbf{x}}_0 = \mathbf{M}^{-1}(\mathbf{p}_0 - \mathbf{C} \dot{\mathbf{x}}_0 - \mathbf{K} \mathbf{x}_0).$$

- With a fixed time step h , compute the constant matrices

$$\mathbf{A} = 2\mathbf{C} + \frac{4}{h}\mathbf{M}, \quad \mathbf{B} = 2\mathbf{M}, \quad \mathbf{K}^+ = \frac{2}{h}\mathbf{C} + \frac{4}{h^2}\mathbf{M}.$$

Constant Acceleration, stepping

- Starting with $i = 0$, compute the effective force increment,

$$\Delta \hat{\mathbf{p}}_i = \mathbf{p}_{i+1} - \mathbf{p}_i + \mathbf{A}\dot{\mathbf{x}}_i + \mathbf{B}\ddot{\mathbf{x}}_i,$$

the tangent stiffness \mathbf{K}_i and the current incremental stiffness,

$$\hat{\mathbf{K}}_i = \mathbf{K}_i + \mathbf{K}^+.$$

- For linear systems, it is

$$\Delta \mathbf{x}_i = \hat{\mathbf{K}}_i^{-1} \Delta \hat{\mathbf{p}}_i,$$

for a non linear system $\Delta \mathbf{x}_i$ is produced by the modified Newton-Raphson iteration procedure.

- The state vectors at the end of the step are

$$\mathbf{x}_{i+1} = \mathbf{x}_i + \Delta \mathbf{x}_i, \quad \dot{\mathbf{x}}_{i+1} = 2 \frac{\Delta \mathbf{x}_i}{h} + \dot{\mathbf{x}}_i$$

Constant Acceleration, new step

- Increment the step index, $i = i + 1$.
- Compute the accelerations using the equation of equilibrium,

$$\ddot{\mathbf{x}}_i = \mathbf{M}^{-1}(\mathbf{p}_i - \mathbf{C} \dot{\mathbf{x}}_i - \mathbf{K} \mathbf{x}_i).$$

- Repeat the substeps detailed in the previous slide.

Modified Newton-Raphson

■ Initialization

$$\mathbf{y}_0 = \mathbf{x}_i$$
$$\Delta \mathbf{R}_1 = \Delta \hat{\mathbf{p}}_i$$

$$\mathbf{f}_{S,0} = \mathbf{f}_S(\text{system state})$$
$$\mathbf{K}_T = \hat{\mathbf{K}}_i$$

■ For $j = 1, 2, \dots$

$$\mathbf{K}_T \Delta \mathbf{y}_j = \Delta \mathbf{R}_j$$

$\rightarrow \Delta \mathbf{y}_j$ (test for convergence)

$$\Delta \dot{\mathbf{y}}_j = \dots$$

$$\dot{\mathbf{y}}_j = \dot{\mathbf{y}}_{j-1} + \Delta \dot{\mathbf{y}}_j$$

$$\mathbf{y}_j = \mathbf{y}_{j-1} + \Delta \mathbf{y}_j,$$

$$\mathbf{f}_{S,j} = \mathbf{f}_S(\text{updated system state})$$

$$\Delta \mathbf{f}_{S,j} = \mathbf{f}_{S,j} - \mathbf{f}_{S,j-1} - (\mathbf{K}_T - \mathbf{K}_i) \Delta \mathbf{y}_j$$

$$\Delta \mathbf{R}_{j+1} = \Delta \mathbf{R}_j - \Delta \mathbf{f}_{S,j}$$

■ Return the value $\Delta \mathbf{x}_i = \mathbf{y}_j - \mathbf{x}_i$

A suitable convergence test is

$$\frac{\Delta \mathbf{R}_j^T \Delta \mathbf{y}_j}{\Delta \hat{\mathbf{p}}_i^T \Delta \mathbf{x}_{i,j}} \leq \text{tol}$$

**Wilson's Theta
Method**

Wilson's Theta Method

The linear acceleration method is significantly more accurate than the constant acceleration method, meaning that it is possible to use a longer time step to compute the response of a *SDOF* system within a required accuracy.

On the other hand, the method is not safely applicable to *MDOF* systems due to its numerical instability.

Definitions

Consider the case of a structure where the supports are subjected to *assigned* displacements histories, $u_i = u_i(t)$.

To solve this problem, we start with augmenting the degrees of freedom with the support displacements.

We denote the superstructure *DOF* with \mathbf{x}_T , the support *DOF* with \mathbf{x}_g and we have a global displacement vector \mathbf{x} ,

$$\mathbf{x} = \begin{Bmatrix} \mathbf{x}_T \\ \mathbf{x}_g \end{Bmatrix}.$$

Example

We decompose the vector of displacements into two contributions, a static contribution and a dynamic contribution, attributing the *given* support displacements to the static contribution.

$$\begin{Bmatrix} \mathbf{x}_T \\ \mathbf{x}_g \end{Bmatrix} = \begin{Bmatrix} \mathbf{x}_S \\ \mathbf{x}_g \end{Bmatrix} + \begin{Bmatrix} \mathbf{x} \\ \mathbf{0} \end{Bmatrix}$$

where \mathbf{x} is the usual *relative displacements* vector.

Determination of static components

Because the \mathbf{x}_g are given, we can write two matricial equations that give us the static superstructure displacements and the forces we must apply to the supports,

$$\begin{aligned}\mathbf{K}\mathbf{x}_s + \mathbf{K}_g\mathbf{x}_g &= \mathbf{0} \\ \mathbf{K}_g^T\mathbf{x}_s + \mathbf{K}_{gg}\mathbf{x}_g &= \mathbf{p}_g\end{aligned}$$

From the first equation we have

$$\mathbf{x}_s = -\mathbf{K}^{-1}\mathbf{K}_g\mathbf{x}_g$$

and from the second we have

$$\mathbf{p}_g = (\mathbf{K}_{gg} - \mathbf{K}_g^T\mathbf{K}^{-1}\mathbf{K}_g)\mathbf{x}_g$$

Truncation

Going back to the EOM

We need the first row of the two matrix equation of equilibrium,

$$\begin{bmatrix} \mathbf{M} & \mathbf{M}_g \\ \mathbf{M}_g^T & \mathbf{M}_{gg} \end{bmatrix} \begin{Bmatrix} \ddot{\mathbf{x}}_T \\ \ddot{\mathbf{x}}_g \end{Bmatrix} + \begin{bmatrix} \mathbf{K} & \mathbf{K}_g \\ \mathbf{K}_g^T & \mathbf{K}_{gg} \end{bmatrix} \begin{Bmatrix} \mathbf{x}_T \\ \mathbf{x}_g \end{Bmatrix} = \begin{Bmatrix} \mathbf{0} \\ \mathbf{p}_g \end{Bmatrix}$$

substituting $\mathbf{x}_T = \mathbf{x}_s + \mathbf{x}$ in the first row

$$\mathbf{M}\ddot{\mathbf{x}} + \mathbf{M}\ddot{\mathbf{x}}_s + \mathbf{M}_g\ddot{\mathbf{x}}_g + \mathbf{K}\mathbf{x} + \mathbf{K}\mathbf{x}_s + \mathbf{K}_g\mathbf{x}_g = \mathbf{0}$$

by the equation of static equilibrium, $\mathbf{K}\mathbf{x}_s + \mathbf{K}_g\mathbf{x}_g = \mathbf{0}$ we can simplify

$$\mathbf{M}\ddot{\mathbf{x}} + \mathbf{M}\ddot{\mathbf{x}}_s + \mathbf{M}_g\ddot{\mathbf{x}}_g + \mathbf{K}\mathbf{x} = \mathbf{M}\ddot{\mathbf{x}} + (\mathbf{M}_g - \mathbf{M}\mathbf{K}^{-1}\mathbf{K}_g)\ddot{\mathbf{x}}_g + \mathbf{K}\mathbf{x} = \mathbf{0}.$$

Example, cont.

The stiffness matrix is found by inversion,

$$\mathbf{K} = \frac{3EJ}{13L^3} \begin{bmatrix} +7.0000 & +12.0000 & -16.0000 \\ +12.0000 & +80.0000 & -46.0000 \\ -16.0000 & -46.0000 & +44.0000 \end{bmatrix}.$$

We are interested in the partitions \mathbf{K}_{xx} and \mathbf{K}_{xg} :

$$\mathbf{K}_{xx} = \frac{3EJ}{13L^3} \begin{bmatrix} +7.0000 & +12.0000.0000 \\ +12.0000 & +80.0000.0000 \end{bmatrix}, \quad \mathbf{K}_{xg} = \frac{3EJ}{13L^3} \begin{bmatrix} -16 \\ -46 \end{bmatrix}.$$

The influence matrix is

$$\mathbf{E} = -\mathbf{K}_{xx}^{-1} \mathbf{K}_{xg} = \frac{1}{16} \begin{bmatrix} 28.0000 \\ 5.0000 \end{bmatrix},$$

please compare \mathbf{E} with the last column of the flexibility matrix, \mathbf{F} .

Consider the vector of support accelerations,

$$\ddot{\mathbf{x}}_g = \{\ddot{x}_{gl}, \quad l = 1, \dots, N_g\}$$

and the effective load vector

$$\mathbf{p}_{eff} = -\mathbf{M}\mathbf{E}\ddot{\mathbf{x}}_g = -\sum_{l=1}^{N_g} \mathbf{M}\mathbf{e}_l \ddot{x}_{gl}(t).$$

We can write the modal equation of motion for mode number n

$$\ddot{q}_n + 2\zeta_n \omega_n \dot{q}_n + \omega_n^2 q_n = -\sum_{l=1}^{N_g} \Gamma_{nl} \ddot{x}_{gl}(t)$$

where

$$\Gamma_{nl} = \frac{\boldsymbol{\psi}_n^T \mathbf{M} \mathbf{e}_l}{M_n^*}$$

The solution $q_n(t)$, with the notation we used previously, is hence

$$q_n(t) = \sum_{l=1}^{N_g} \Gamma_{nl} D_{nl}(t),$$

D_{nl} being the response function for ζ_n and ω_n due to the ground excitation \ddot{x}_{gl} .

Response Analysis, cont.

The total displacements \mathbf{x}_T are given by two contributions, $\mathbf{x}_T = \mathbf{x}_S + \mathbf{x}$, the expression of the contributions are

$$\mathbf{x}_S = \mathbf{E}\mathbf{x}_g(t) = \sum_{l=1}^{N_g} \mathbf{e}_l x_{gl}(t),$$

$$\mathbf{x} = \sum_{n=1}^N \sum_{l=1}^{N_g} \boldsymbol{\psi}_n \Gamma_{nl} D_{nl}(t),$$

and finally we have

$$\mathbf{x}_T = \sum_{l=1}^{N_g} \mathbf{e}_l x_{gl}(t) + \sum_{n=1}^N \sum_{l=1}^{N_g} \boldsymbol{\psi}_n \Gamma_{nl} D_{nl}(t).$$

For a computer program, the easiest way to compute the nodal forces is

- a)* compute, element by element, the nodal displacements by \mathbf{x}_T and \mathbf{x}_g ,
- b)* use the element stiffness matrix to compute nodal forces,
- c)* assemble element nodal loads into global nodal loads.

That said, let's see the analytical development...

Forces, cont.

The forces on superstructure nodes due to deformations are

$$\mathbf{f}_s = \sum_{n=1}^N \sum_{l=1}^{N_g} \Gamma_{nl} \mathbf{K} \boldsymbol{\psi}_n D_{nl}(t)$$

$$\mathbf{f}_s = \sum_{n=1}^N \sum_{l=1}^{N_g} (\Gamma_{nl} \mathbf{M} \boldsymbol{\psi}_n) (\omega_n^2 D_{nl}(t)) = \sum \sum r_{nl} A_{nl}(t)$$

the forces on support

$$\mathbf{f}_{gs} = \mathbf{K}_g^T \mathbf{x}_T + \mathbf{K}_{gg} \mathbf{x}_g = \mathbf{K}_g^T \mathbf{x} + \mathbf{p}_g$$

or, using $\mathbf{x}_s = \mathbf{E} \mathbf{x}_g$

$$\mathbf{f}_{gs} = \left(\sum_{l=1}^{N_g} \mathbf{K}_g^T \mathbf{e}_l + \mathbf{K}_{gg,l} \right) \mathbf{x}_{gl} + \sum_{n=1}^N \sum_{l=1}^{N_g} \Gamma_{nl} \mathbf{K}_g^T \boldsymbol{\psi}_n D_{nl}(t)$$

The stiffness matrix for the 10x10 model is

$$\mathbf{K}_{10 \times 10} = \frac{EJ}{L^3} \begin{bmatrix} 12 & -12 & 0 & 0 & 0 & 6L & 6L & 0 & 0 & 0 \\ -12 & 24 & -12 & 0 & 0 & -6L & 0 & 6L & 0 & 0 \\ 0 & -12 & 24 & -12 & 0 & 0 & -6L & 0 & 6L & 0 \\ 0 & 0 & -12 & 24 & -12 & 0 & 0 & -6L & 0 & 6L \\ 0 & 0 & 0 & -12 & 12 & 0 & 0 & 0 & -6L & -6L \\ 6L & -6L & 0 & 0 & 0 & 4L^2 & 2L^2 & 0 & 0 & 0 \\ 6L & 0 & -6L & 0 & 0 & 2L^2 & 8L^2 & 2L^2 & 0 & 0 \\ 0 & 6L & 0 & -6L & 0 & 0 & 2L^2 & 8L^2 & 2L^2 & 0 \\ 0 & 0 & 6L & 0 & -6L & 0 & 0 & 2L^2 & 8L^2 & 2L^2 \\ 0 & 0 & 0 & 6L & -6L & 0 & 0 & 0 & 2L^2 & 4L^2 \end{bmatrix}$$

Example, cont.

The first product of the static condensation procedure is the linear mapping between translational and rotational degrees of freedom, given by

$$\vec{\phi} = \frac{1}{56L} \begin{bmatrix} 71 & -90 & 24 & -6 & 1 \\ 26 & 12 & -48 & 12 & -2 \\ -7 & 42 & 0 & -42 & 7 \\ 2 & -12 & 48 & -12 & -26 \\ -1 & 6 & -24 & 90 & -71 \end{bmatrix} \vec{\chi}.$$

Example, cont.

Following static condensation and reordering rows and columns, the partitioned stiffness matrices are

$$\mathbf{K} = \frac{EJ}{28L^3} \begin{bmatrix} 276 & 108 \\ 108 & 276 \end{bmatrix},$$

$$\mathbf{K}_g = \frac{EJ}{28L^3} \begin{bmatrix} -102 & -264 & -18 \\ -18 & -264 & -102 \end{bmatrix},$$

$$\mathbf{K}_{gg} = \frac{EJ}{28L^3} \begin{bmatrix} 45 & 72 & 3 \\ 72 & 384 & 72 \\ 3 & 72 & 45 \end{bmatrix}.$$

The influence matrix is

$$\mathbf{E} = \mathbf{K}^{-1}\mathbf{K}_g = \frac{1}{32} \begin{bmatrix} 13 & 22 & -3 \\ -3 & 22 & 13 \end{bmatrix}.$$

Example, cont.

The eigenvector matrix is

$$\mathbf{\Psi} = \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}$$

the matrix of modal masses is

$$\mathbf{M}^* = \mathbf{\Psi}^T \mathbf{M} \mathbf{\Psi} = m \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$

the matrix of the non normalized modal participation coefficients is

$$\mathbf{L} = \mathbf{\Psi}^T \mathbf{M} \mathbf{E} = m \begin{bmatrix} -\frac{1}{2} & 0 & \frac{1}{2} \\ \frac{5}{16} & \frac{11}{8} & \frac{5}{16} \end{bmatrix}$$

and, finally, the matrix of modal participation factors,

$$\mathbf{\Gamma} = (\mathbf{M}^*)^{-1} \mathbf{L} = \begin{bmatrix} -\frac{1}{4} & 0 & \frac{1}{4} \\ \frac{5}{32} & \frac{11}{16} & \frac{5}{32} \end{bmatrix}$$

Example, cont.

Denoting with $D_{ij} = D_{ij}(t)$ the response function for mode i due to ground excitation \ddot{x}_{gj} , the response can be written

$$\begin{aligned}\mathbf{x} &= \begin{pmatrix} \psi_{11}\left(-\frac{1}{4}D_{11} + \frac{1}{4}D_{13}\right) + \psi_{12}\left(\frac{5}{32}D_{21} + \frac{5}{32}D_{23} + \frac{11}{16}D_{22}\right) \\ \psi_{21}\left(-\frac{1}{4}D_{11} + \frac{1}{4}D_{13}\right) + \psi_{22}\left(\frac{5}{32}D_{21} + \frac{5}{32}D_{23} + \frac{11}{16}D_{22}\right) \end{pmatrix} \\ &= \begin{pmatrix} -\frac{1}{4}D_{13} + \frac{1}{4}D_{11} + \frac{5}{32}D_{21} + \frac{5}{32}D_{23} + \frac{11}{16}D_{22} \\ -\frac{1}{4}D_{11} + \frac{1}{4}D_{13} + \frac{5}{32}D_{21} + \frac{5}{32}D_{23} + \frac{11}{16}D_{22} \end{pmatrix}.\end{aligned}$$
